

Predicting Formal Protest Petitions Against Housing Development

Evidence from Austin, Texas

Daniel Hardesty Lewis

M.S. Candidate, Urban Planning

Columbia University

April 16, 2026

Housing Crisis and Local Opposition

The Affordability Problem

- Austin grew $\approx 40\%$ between 2010–2024.
- New housing requires discretionary rezoning approval.
- Projects face public hearings and organized opposition.

The Political Mechanism

Texas law gave adjacent property owners a formal institutional veto: the **protest petition**.

The Protest Petition: An Institutional Veto

Texas LGC Chapter 211: The 20% Rule

- Owners of 20% of land within 200ft may file written protest.
- A valid petition triggers a supermajority ($\frac{3}{4}$) council vote.
- Post-2014 council (11 members): 6 votes → 9 required.
- 21 states maintain similar petition statutes.

A localized minority can block citywide housing decisions.

PETITION				
Case Number:	C14-2007-0131	Date:	July 29, 2008	
5506 WALLER ST, 807 E 16TH ST & 908 E 15TH ST

Validated By: Stacy Meeks			Total Area of Petitioners:	Total %: 20.47%

Sample formal protest petition record

Why Petitions Matter: Institutional Costs

Reduced-Form Discontinuity at the 20% Threshold

- Running variable: reconstructed petition-share.
- Outcome: council processing time.
- Estimator: triangular-kernel WLS at the 20% margin.

Result: Crossing the threshold adds **42.5 days** (6.1 weeks).

95% CI: [26.4, 58.6] days. McCrary $p > 0.05$.

The Research Question

The Prediction Problem

Can we anticipate protest petitions *before* public hearings using only filing-date records?

Filing-Date Features

- Site geometry: lot area, height/FAR deltas.
- Current vs. requested zoning class.
- Buffer demographics and TCAD appraisals.
- Historical petition rates in the district.

A Sample Case

Feature	Case C14-2018-0156
Gross Site Area	4.92 Acres
Height Request	+15.5 ft
FAR Request	+0.43
Neighborhood	Riverside
Result	Valid Petition

Race/ethnicity excluded from predictive features; reserved for post-hoc equity audits only.

The Rarity Problem

Sample Constraints

- $N = 6783$ cases, 2007–2024.
- Base rate: $\approx 2.6\%$ (1 in 38 cases).
- Test-set positives: $n_{\text{pos}} = 15$.

Sparse positives widen confidence intervals.
The output is a **relative risk ranking**, not a case-level probability.

Evaluation Design

- Train on years $\leq t$; evaluate on years $> t$.
- No random splits: mimics forward administrative use.

Primary metric: PR-AUC

AUROC omitted: 97.4% true negatives artificially inflate it.

Timeline Integrity: As-Of Features

Enforcing the Constraint

- 15+ years of zoning agendas scraped from PDF clerk records.
- Filing dates back-calculated from statutory minimums.
- ACS and TCAD records anchored to publication date.
- $N = 8$ IRB-approved interviews (ACY0820) for institutional grounding.

Research Project Overview

Predicting NIMBYism in Austin's Housing Reform Era

Project Abstract

This research focuses on the development of AI and its impact on the landscape of the region in Austin, Texas. By analyzing public records, public hearings, and zoning applications data, the study seeks to understand the impact of AI on the region's public behavior. The project employs predictive modeling, natural language processing, and qualitative analysis to predict public behavior, identify emerging public issues, and assess the impact of AI on public planning outcomes.

Study Objectives

Identify Patterns: Understand the impact of AI on the region's public behavior and its impact on the landscape of the region.

Evaluate Predictive Tools: Assess whether existing tools and predictive models can accurately forecast public behavior in specific development projects.

Demographic Impact: Understand the impact of AI on the region's public behavior and its impact on the landscape of the region.

Participant Role

We are seeking perspectives from urban planners, developers, neighborhood advocates, and community organizers.

Availability: A 1-hour interview is required, conducted either in person or via phone.

Topic: Your experience with zoning, development planning tools, and community engagement in Austin.

Data Privacy and Ethical Standards

This study has been approved by the Columbia University Institutional Review Board under Protocol 08-0016.

Participation is entirely voluntary.

You may decline to answer any specific question or discontinue the interview at any time.

Identification with a key identifier will be required for publication of the study's findings. Your participation is essential.

Predicting Resistance: Filing-Date Results

Tree Ensembles Dominate at the Top of the Risk Ranking

Operational Utility: Triage in Practice

Top-Decile Risk Ranking

- Flag the highest-risk 10% of cases.
- Precision: **25.4%** (CI: 16.1%–37.8%).
- Lift: **9.9x** over the base rate.
- Captures 15 true positives in 59 flagged cases.

Reviewing flagged cases is **nearly 10x** more likely to surface a genuine petition case.

Appropriate Uses

- ✓ Prioritize outreach for high-risk cases.
- ✓ Flag cases for early negotiation.
- × Hard probability cutoffs.
- × Developer site-screening.

Ethics Warning: This model ranks risk. It should not be used to pre-screen sites for developers.

Four-Family Modeling Benchmark

Pre-Registered Architecture Families

Family	Key Property	Selection Criterion
Tree (CatBoost)	Robust to scale diversity; dominant on tabular data	All families tuned to maximize OOD PR-AUC under strict temporal separation.
Deep (Tab-Net/MLP)	Overfits without heavy L2 regularization	
Linear (L2)	Competitive at T+0; decays at long horizons	Primary model (CatBoost) pre-specified as best OOD PR-AUC subject to lowest ECE.
Robust (V-REx)	Distributionally robust; causal-stability baseline	No model-shopping after seeing results.

What Drives Petition Risk

Key Finding

Tree models allocate over 80% of weight to **socio-demographic** clusters: neighborhood demographics, income, and housing tenure.

Physical parcel attributes matter far less than **who lives nearby**.

Deep models invert this, concentrating weight on parcel scale and valuation.

Comparative Primary Reliance: Top Feature Clusters Across Architectures

Architecture Determines Feature Reliance

Architecture-Dependent Reliance

- Trees: >80% weight on socio-demographic clusters.
- Deep models: shift toward physical and geographic attributes.
- Same data, same task: different internal logic.

Algorithm selection is a normative choice about which features are prioritized.

Temporal Drift and Neighborhood Agency

When Does the Model Break?

- Linear models collapse at T+3 horizons and beyond.
- Tree ensembles degrade more gracefully.

The 2022 Dip

- PR-AUC drops sharply across all families in 2022.
- Consistent with pandemic-era filing disruptions reaching the evaluation window.
- Not a causal claim.

Performance sensitivity to ambient shocks is *consistent with* mobilization being a strategic social choice.

Signal Dilution: When Retraining Hurts

The Paradox

- Pre-2018 models achieve $\sim 34\times$ lift in 2024.
- Retraining on modern data degrades lift to $\sim 19\times$.

Post-ordinance labels starve the model of positive examples. The frozen legacy model preserves spatial sorting intelligence from an active institutional era.

Qualitative Context: Motive Blindness

What the Algorithm Cannot Distinguish

- Exclusionary NIMBYism (affluent West Austin blocking density).
- Anti-displacement resistance (East Austin protecting tenants).

Same risk weight; opposite social meaning.

Practitioner Perspectives (IRB ACYY0820, $N = 8$)

- *“Haters are overrepresented and silent supporters are underrepresented.”* (Beaudet)
- Rigid cutoffs fail to identify communities in actual need. (Torrado)
- Probability thresholds are *“ethically hazardous.”* (Tomko)

COLUMBIA UNIVERSITY Graduate School of Architecture, Planning and Preservation	Environmental Studies and Sustainable Urban
Predicting NIMBYism in Austin's Housing Reform Era	
Purpose	
To explore the role of political culture and institutional arrangements in shaping the outcomes of housing reform in Austin and how the outcomes of political and institutional arrangements shape the outcomes of housing reform.	
Opening	
1. What are the political and institutional arrangements that shape the outcomes of housing reform in Austin? 2. How do the political and institutional arrangements shape the outcomes of housing reform? 3. How do the political and institutional arrangements shape the outcomes of housing reform?	
Part 2: Background and Data	
1. Can you briefly describe your current role and how it relates to housing, planning, or land use in Austin? 2. How long have you been working in the field of housing in Austin? 3. In your role, what kinds of development or housing decisions do you most often think about?	
Part 3: Experiences with Neighborhood Opposition	
1. What are the kinds of neighborhood opposition to housing or development that you see in Austin, and what are the most common? 2. Can you describe a recent case in which neighborhood opposition played a major role? What happened? 3. In your experience, what types of groups are most likely to get into opposition? 4. What are the most common reasons for neighborhood opposition to housing or development?	
Part 4: Perceptions of Biasness and Discrimination	
1. Do you think there is potential for housing opposition to be biased against certain groups? 2. If so, which groups are most overrepresented or underrepresented in the opposition? 3. How do you think opposition is affected by race, class, or other factors in housing and planning decisions?	
Part 5: Views on Predictive and Algorithmic Tools	
1. How do you see the use of predictive tools in housing and planning decisions? 2. How do you see the use of predictive tools in housing and planning decisions? 3. How do you see the use of predictive tools in housing and planning decisions? 4. How do you see the use of predictive tools in housing and planning decisions? 5. How do you see the use of predictive tools in housing and planning decisions?	

IRB-Approved Interview Protocol

Limitations

Methodological

- **Chilling effects:** Only filed cases are observed; pre-emptive withdrawals are invisible. IPW failed overlap diagnostics.
- **Timestamp imputation:** Milestone dates approximated from statutory minimums.
- **Unobserved certification:** Outcome is reconstructed area share, not the clerk's legal determination.

Ethical and Governance

- **Proxy discrimination:** Neighborhood income and demographics encode class and race dynamics even without protected-class inputs.
- **Motive blindness:** Cannot separate exclusionary NIMBYism from anti-displacement resistance.
- **External validity:** Parameters are Austin-specific and pre-HB 24 only.

Conclusion

What we showed

- Crossing 20% adds 42.5 days of processing time: the outcome is worth predicting.
- Filing-date data ranks petition risk above chance (PR-AUC = 0.718, CI: [0.48, 0.91]), with top-decile lift of 9.9x.
- Algorithm choice determines which feature clusters drive predictions, a normative decision.

What surprised us

- Retraining on modern data degrades lift; legacy models preserve spatial sorting intelligence.
- Performance ceilings are consistent with mobilization as a strategic social choice.

What it implies

- Predictions belong in relative triage rankings, not case-level probability thresholds.
- Methodology is portable; Austin-specific parameters are not.

Implications: A Now-Closed Policy Window

The HB 24 Shift (September 1, 2025)

- Texas HB 24 exempted residential upzonings from the supermajority requirement.
- The 20% institutional veto no longer applies to the most contested case types.
- This thesis maps a specific, now-closed historical era of minority veto power.

What travels forward

- Methodology (time-stamped features, temporal holdouts, semantic clustering, qualitative integration) is portable to other discretionary review systems.
- Iowa, Oklahoma, and Arizona retain similar petition statutes. The framework applies wherever institutional veto mechanisms create predictable opposition patterns.
